The University of Moratuwa, Sri Lanka

November 23, 2016

- ① In representing and analyzing LTI systems, our approach has been to decompose the system inputs into a linear combination of basic signals and exploit the fact that for a linear system, the response is the same linear combination of the responses to the basic inputs.
- ② The convolution sum and the convolution integral req out of the particular choice of the basic signals, delayed unit impulses.
- ③ This choice has the advantage that for systems that are time invariant in addition to being linear, once the response to an impulse at one time position is known, then the response id know at all time positions.

# Complex Exponentials with Unity Magnitude as Basic Signals

- ① When we select complex exponential with unity magnitude as the basic signals, the decomposition of this form of a periodic signal is the Fourier series.
- ② For aperiodic signals, it becomes the Fourier transform.
- ③ In latter lectures, we will generalize this representation to Laplace transform for continuous-time signals and  $z$ -transform for discrete-time signals.
